ABSTRACT: The first structural determination is described of a cyclic phosphazene,  $N_3P_3Cl_4(i\text{-Pr})H$ , (VI), which contains both a hydrogen atom and an alkyl group as substituents attached to phosphorus. Compound VI contains a planar phosphazene ring with a curious alternation of P-N bond lengths at progressively greater distances from the  $P(i\text{-Pr})H$  unit and with corresponding distortions in the bond angles within the ring. The longest P-N bonds are those connected to the  $P(i\text{-Pr})H$  unit. The phosphorus-hydrogen bond length is  $1.26(3)$  Å, the phosphorus-carbon bond distance is  $1.76(5)$  Å, and the H-P-C bond angle is  $108.8(7)^\circ$ . The structural features of the molecule can be understood in terms of crystal packing forces and  $\pi$  bonding hypotheses. Crystals of VI were orthorhombic with the space group  $P_{2_1}^21^21^2$  and with  $a = 6.128(4)$  Å,  $b = 11.485(2)$  Å, and  $c = 17.467(3)$  Å, and  $Z = 4$ . The final  $R_1$  and  $R_2$  factors were 0.043 and 0.045 respectively.

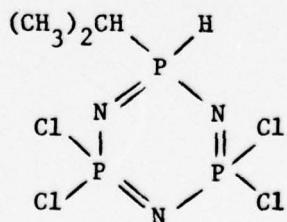

Scheme I

## INTRODUCTION

In earlier papers we described the synthesis of a new class of phosphazene compounds that contain a hydrogen atom as a side group bonded directly to phosphorus. These hydrido-alkyl-phosphazenes (III) are synthesized readily via the reaction of hexachlorocyclotriphosphazene (I) with alkyl Grignard reagents in the presence of  $[(n\text{-Bu})_3\text{PCuI}]_4$ , followed by treatment of the resultant metalloc-phosphazene intermediate (II) with iso-propanol<sup>2,3</sup> (Scheme I). Such hydrido-phosphazene compounds (III) have since proved to be important intermediates for the synthesis of a variety of 1-halo-1-alkyl-tetrachlorocyclotriphosphazenes (V),<sup>4-6</sup> including those which contain phosphorus-iodine bonds. This approach to phosphazene synthesis via II has also yielded numerous 1,1-dialkylcyclotriphosphazenes (IV) including a number with unsaturated alkyl units.<sup>7,8</sup>

Scheme I

We describe here the first X-ray structural determination of a hydrido-cyclophosphazene (VI). This particular compound was chosen as a prototype for

VI

structural studies because it is less sensitive to air and moisture than other hydridophosphazenes of this type.<sup>2,3</sup> The structural determination was carried

out in an attempt to answer the following questions. (1) Is the hydrogen atom linked directly to a phosphorus atom? (Earlier infrared and NMR evidence had provided a strong indication of the presence of a direct P-H bond,<sup>2,3</sup> but confirmatory evidence was needed). (2) Does the small steric size of a hydrogen atom compared to, say, chlorine or alkyl induce unusual changes in the geometry of the groups attached to phosphorus? (3) What effect, if any, does the hydrogen atom exert on the lengths of the phosphorus-nitrogen bonds, or on the overall geometry of the molecule? (4) Is the hydrogen atom in VI especially sterically shielded in a way that would explain its higher than expected stability to air and moisture?

#### EXPERIMENTAL SECTION

##### Synthesis of 1-Hydrido-1-iso-propyl-tetrachlorocyclotriphosphazene (VI).

This compound was prepared by the reaction of hexachlorocyclotriphosphazene (I) with i-PrMgCl, in tetrahydrofuran, in the presence of  $[(n\text{-Bu})_3\text{PCuI}]_4$ , followed by treatment of the intermediate II ( $\text{R} = \text{i-Pr}$ ) with i-PrOH, as reported earlier.<sup>2,3</sup> Crystals of VI suitable for single crystal X-ray diffraction were grown slowly from a saturated solution in hexane at -10°C.

Crystallographic Data Collection. A clear fragment of VI, with dimensions ca. 0.4 x 0.4 x 0.5 mm, was mounted on a glass fiber and was placed in a glass capillary tube under an atmosphere of dry nitrogen. Precession photographs were obtained with this crystal with the use of zirconium-filtered molybdenum K $\alpha$  radiation ( $\lambda$  0.71069 Å). These photographs indicated that the crystal was orthorhombic (Laue symmetry  $m\bar{m}m$ ) with the spindle axis parallel to the crystallographic c axis. The observed systematic presences:  $h00$ ,  $h = 2n$ ;  $0k0$ ,  $k = 2n$ ;  $001$ ,  $l = 2n$ , gave  $P_{2\bar{1}2\bar{1}2\bar{1}}$  as the space group. A second crystal, with the dimensions ca. 0.2 x 0.2 x 0.25 mm, was mounted as before and was placed on an Enraf-Nonius CAD-4 diffractometer, controlled by PDP8/a computer. Molybdenum X-rays and a graphite monochromator were used. Twenty-five reflections were located and centered using the Enraf-Nonius

program SEARCH. A least squares refinement of the 20 values for these twenty-five reflections gave  $a = 6.128(4)$ ,  $b = 11.485(2)$ ,  $c = 17.467(3) \text{ \AA}$ ,  $\beta = 129.2^\circ$ ;  $d_m = 1.710 \text{ g cm}^{-3}$  (by flotation in tribromomethane/tetrachloromethane mixtures),  $d_c = 1.734 \text{ g cm}^{-3}$ ,  $Z = 4$ . The calculated molecular weight was 320.92. (Theory for VI = 320.886).

Intensity data were collected using a  $0 - 2\theta$  scan mode for all reflections where  $0.01^\circ \leq 2\theta \leq 60^\circ$ . Scan widths were determined with the use of the formula  $(SW) = A + B(\tan \theta)$ , where A is estimated from the mosaic character of the crystal and B accounts for the increase in the width of the peak due to the  $K\alpha_1$  and  $K\alpha_2$  splittings. The values determined for A and B were 0.65 and 0.35 respectively. An increase in the scan angle of 25% on each side of the reflection was employed for measurement of background intensities. The net intensities,  $\tilde{I}$ , were calculated with the use of the formula  $\tilde{I} = CTS - 2(BGR + BGL)$ , where CTS defines the total number of counts and BGR and BGL are the right and left background counts respectively. Reflections for which the ratio  $\sigma(\tilde{I})/\tilde{I} < 2$  were labelled as weak and were automatically rejected by the computer. Three check reflections, measured every 1 h, showed no significant change in intensity throughout the entire data collection. The data were corrected for Lorentz and polarization effects, but no absorption correction was applied. The linear absorption coefficient  $\mu$ , for Mo  $K\alpha$  radiation, was calculated to be  $13.04 \text{ cm}^{-1}$ . Of the 3089 reflections measured, 784 had an intensity greater than  $3\sigma(\tilde{I})$ ,  $896 > 2\sigma(\tilde{I})$  and  $1084 > 1\sigma(\tilde{I})$ . Only those reflections for which  $\tilde{I} > 3\sigma(\tilde{I})$  were used in the refinement.

Solution and Refinement of the Structure. The atomic scattering factors used for all the atoms were those of Cromer and Waber.<sup>9</sup> The function minimized in the least squares refinement was  $\sum \omega(|F_o| - |F_c|)^2$ , where  $\omega = 1/\sigma(F_o)^2$ . The residuals  $R_1$  and  $R_2$  are expressed by the formulae  $R_1 = \sum \left| |F_o| - |F_c| \right| / \sum |F_o|$ , and  $R_2 = \left[ \sum \omega(|F_o| - |F_c|)^2 / \sum \omega(F_o)^2 \right]^{1/2}$ . A three dimensional Patterson synthesis was

used to locate the position of one phosphorus atom. Three cycles of refinement of the positional and isotropic thermal parameters of this atom gave  $R_1 = 0.46$ . A difference Fourier allowed the location of the other two phosphorus atoms in the ring. Three cycles of refinement on these three atoms lowered  $R_1$  to 0.44. Another difference Fourier map revealed the positions of two of the chlorine atoms. Refinement through three cycles with these five atoms gave  $R_1 = 0.34$ . A further difference Fourier allowed the location of the other two chlorine atoms and the three ring nitrogen atoms. Three more cycles of refinement on these ten atoms lowered  $R_1$  to 0.16. Another difference Fourier revealed the positions of the three carbon atoms. Refinement through three more cycles lowered  $R_1$  to 0.10. A final difference Fourier allowed the location of all the hydrogen atoms. The introduction of the hydrogen atoms to the model, combined with a change of the thermal parameters to anisotropic for all non-hydrogen atoms, followed by three final cycles of refinement, gave  $R_1 = 0.043$  and  $R_2 = 0.045$ . The isotropic thermal parameters for all the hydrogen atoms were fixed at  $1.0 \text{ \AA}^2$  more than the isotropic thermal parameters of the atom to which they were bonded.

The refined positional and anisotropic thermal parameters for all non-hydrogen atoms are given in Table I. The hydrogen atom positions and their isotropic thermal parameters are shown in Table II. A listing of the observed and calculated structure factor amplitudes for the 784 reflections used in the refinement appear in Table III, which is recorded in the microfilm and microfiche editions.

Computations were carried out with the use of a PDP 11/34 computer. The perspective and stereoscopic drawings were obtained with the use of VERSATEC plotter. The computer programs used were the Enraf-Nonius "Structural Determination Package" and the Enraf-Nonius version of the ORTEP program.

## RESULTS AND DISCUSSION

General Structural Features of the Molecule. The X-ray structure determination of VI indicated that the phosphazene ring in this molecule is planar. The hydrogen atom and iso-propyl group are bound to one phosphorus atom, P(1), and two chlorine atoms are linked to each of the remaining two phosphorus atoms. The mean P-Cl bond lengths of 1.994 Å and the Cl-P-Cl bond angle of 100.05° are similar to the lengths and angles reported for hexachlorocyclotriphosphazene.<sup>10-12</sup> The general structure of the molecule, together with the numbering system used for all non-hydrogen atoms is shown in Figure 1. A stereoscopic view is shown in Figure 2. The bond distances and angles are listed in Table IV.

Bonding About Phosphorus Atom P(1). The skeletal phosphorus atoms in cyclic phosphazenes usually display a distorted tetrahedral geometry, with a ring angle near 120° and an exocyclic angle near 100°.<sup>13</sup> As shown in Figure 1, the bond angles at P(1) in VI are appreciably distorted from this normal arrangement. Specifically, the N-P-N ring angle is narrowed to 115.6° and the exocyclic C-P-H angle is widened to 108.9°. This cannot be a result of a steric interaction between the side groups because of the small size of the hydrogen linked to P(1) and the particular orientation adopted by the iso-propyl group. Hence, as will be discussed later, the wide exocyclic C-P-H angle is probably a response (scissoring effect) to the narrow N-P(1)-N ring angle which, in turn, may depend on unusual electronic effects within the phosphazene ring.

The P(1)-H(1) bond length is 1.26(3) Å. This distance is shorter than phosphorus-hydrogen bond lengths reported for phosphines. For example, the P-H bond distance in PH<sub>3</sub> was reported<sup>14</sup> to be 1.44 Å. However, this difference is not considered to be significant because of the lack of precision in the location of hydrogen atoms by the X-ray method. A neutron diffraction study<sup>15</sup> has been used to show that the P-H bond distance in PH<sub>4</sub><sup>+</sup> is 1.414 Å.

Orientation of the iso-propyl Group. The iso-propyl group bonded to P(1) occupied an unusual orientation. The group was positioned in such a way that carbon atom C(2) was located over the phosphazene ring and C(3) was displaced to the side of an imaginary plane through P(1), C(1), C(2) and N(4). Hydrogen atoms H(21) and H(22) lie adjacent to nitrogen atoms N(6) and N(2) respectively. The distances N(6)•••H(21) and N(2)•••H(22) are almost exactly the sum of the van der Waals radii for these atoms (2.75 Å). Thus, the orientation of the iso-propyl group could be a response to these van der Waals interactions, or even a consequence of weak hydrogen bonding.

However, it was concluded that crystal packing forces are probably responsible for this conformation. A variable temperature  $^{13}\text{C}$  NMR study<sup>16</sup> showed that no particular conformation for the iso-propyl group was preferred in solution, even at temperatures as low as -80°C. The spectrum - a doublet of triplets [P-CH(CH<sub>3</sub>)<sub>2</sub>] centered at 29.53 ppm, ( $J_{\text{PC}} = 90.1$  Hz,  $J_{\text{PNPC}} = 3.2$  Hz) and a singlet [P-CH(CH<sub>3</sub>)<sub>2</sub>] at 12.93 ppm - did not change over the temperature range of +40°C to -80°C. Thus the unusual orientation found for the iso-propyl group is a phenomenon of the solid state system and is not an intrinsic characteristic of VI in the solution state. In solution, the iso-propyl group may exert some steric shielding effect on the reactivity of the hydrido function.

The P(1)-C(1) bond length was found to be 1.76(5) Å. This distance is similar to phosphorus-carbon bond lengths that have been determined for other alkyl-halo-cyclophosphazenes (Table V).<sup>17-21</sup> The C(1)-C(2) and C(1)-C(3) bond lengths, of 1.540 Å and 1.537 Å respectively, are typical for carbon-carbon single bonds.<sup>22</sup>

Bonding Within the Phosphazene Ring. Three distinctly different P-N bond lengths were found in the skeletal ring of VI. The two P-N bonds connected to P(1), (the phosphorus atom bearing the hydrogen and iso-propyl group),

were longer (1.61 Å), than the other P-N bonds. In fact, an alternation in longer and shorter bonds existed for the P-N bonds located at increasing distances from P(1). Thus P(1)-N(2) and P(1)-N(6) were 1.61 Å, N(6)-P(5) and N(2)-P(3) were 1.55 Å, and P(3)-N(4) and P(5)-N(4) were 1.58 Å. (This last difference is considered to be significant). The lengths of the P-N bonds furthest from P(1) are very similar to those determined for hexachlorocyclotriphosphazene.<sup>10-12</sup> The variation in P-N bond lengths found in compound VI has been observed for other partially alkylated cyclophosphazenes<sup>17-21</sup> and it has been ascribed to the influence by the less-electronegative substituents at P(1) on the π-bonding in the ring.<sup>19-21, 23, 24</sup> We agree with this interpretation.

The unequal bond lengths within the six membered phosphazene ring lead inevitably to distortions in the endocyclic bond angles away from 120°. The decrease in the N(6)-P(1)-N(2) bond angle (to 115.6°) has already been mentioned. However, the N(2)-P(3)-N(4) and N(4)-P(5)-N(6) angles (mean value 120.04°) are close to those found in  $(NPCl_2)_3$ <sup>10-12</sup> and in  $(NPF_2)_3$ .<sup>25</sup> The exocyclic Cl-P(3)-Cl and Cl-P(5)-Cl angles (100.05°) are similar to those found in  $(NPCl_2)_3$ .<sup>10-12</sup> Comparisons between the structural parameters for VI and for closely related phosphazenes are listed in Table V.

ACKNOWLEDGEMENT. We thank the Office of Naval Research for support of this work through Grant No. N00014-75-C-0685.

SUPPLEMENTARY MATERIAL AVAILABLE. Table III. A complete listing of the observed and calculated structure factor amplitudes (6 pages). Ordering information is given on any current Masthead page.
